APPARATUS AND METHOD FOR SETTING PRESSURE IN A FUEL DELIVERY SYSTEM

CROSS REFERENCE TO RELATED APPLICATIONS

This application is related to commonly owned and assigned
United States Patent Application serial no. _____, attorney docket no. DP-
309706, entitled: "COMBINATION VALVE FOR FUEL SYSTEM" filed
5 contemporaneously with this application. The contents of which are
incorporated herein by reference thereto.

TECHNICAL FIELD

This application relates to fuel systems for vehicles, and in
10 particular, a fuel delivery system for a vehicle.

BACKGROUND

It is known to provide a fuel tank in a vehicle to hold a reservoir
of fuel to be used by an engine of the vehicle. It is also known to provide a fuel
15 pump assembly inside the fuel tank to pump fuel from the reservoir to the
engine. Typically, the fuel pump includes a one way check valve configured to
allow fuel to exit the fuel pump or fuel tank via a fuel line under certain
conditions. Generally, a forward flow check valve consists of a checking device,
typically a plunger, such as a pintel having a seal, and a seat that when in
20 contact form a leak proof seal. The pintel and seal are forced against the seat
with a spring that provides the proper force to maintain pintel and seal to seat
contact during no flow and low-pressure forward flow conditions. This force
prevents flow from exiting the fuel tank when the vehicle fuel line is removed or
when a sufficient amount of pressure is not in the line.

DP-309885

During a vehicle shut down pressure in the fuel delivery system past or downstream from the check valve of the fuel pump may increase due to heating of the fuel in the line, which may occur due to heat radiated from the engine after it is shut down. In order to provide a release for this pressure in a vehicle shut down situation a release valve can be positioned to provide the pressure release when a threshold value has been reached. The pressure release valve will allow fuel to be released back into the fuel reservoir. However, such a pressure release downstream from the check valve will cause air to be allowed into the fuel circuit due to the releasing of fuel under pressure. Also, as the fuel in the line is cooled over time a vacuum can be created in the fuel circuit downstream from the check valve caused by the reduction in volume of liquid fuel. Moreover, if the vacuum in the fuel circuit is not sufficient to overcome the pressure setting of the check valve (e.g., spring closing force) a loss of fuel or fuel pressure may occur in the circuit after the check valve. Such a loss of fuel or pressure will have to be overcome during a starting sequence when the pump again starts to pump fuel into the circuit. Overcoming this loss of fuel or pressure in the circuit may cause the starting sequence to take longer than a starting sequence wherein there is no loss of fuel or pressure in the circuit.

In order to ensure that fuel system pressure is maintained below a certain pressure in the fuel rail during a vehicle shut down, a fuel pressure regulator can be modified to have an expensive lapping process to ensure that a desired fuel pressure is maintained in the fuel rail during vehicle shut down. However, the pressure release of the regulator will be at the same value as the regulator is designed to provide during pumping of the fuel in an engine running or starting sequence.

DP-309885

Accordingly, it is desirable to maintain a desirable fuel pressure in the fuel rail during vehicle shut down without modifying the fuel pressure regulator and limiting the number of valves positioned in the circuit.

5 SUMMARY:

The above discussed and other drawbacks and deficiencies are overcome or alleviated by a fuel delivery system for a vehicle having an engine, comprising: a pump being configured to provide fuel to the engine; a fluid pathway being in fluid communication with an outlet port of said pump at one
10 end; a regulator being disposed in the fluid pathway, the regulator regulating pressure of the fuel when said pump is pumping fuel into the fluid pathway; and a combination valve being disposed in the fluid pathway, the regulator being located between the combination valve and the outlet port of the pump, wherein the combination valve provides a check valve configured to allow fuel flow in a
15 first direction and a pressure relief valve configured to allow fuel flow in a second direction, the first direction being opposite to the second direction and the first direction being the same direction fuel is pumped in the fluid pathway by the pump.

20 A method for maintaining fuel pressure in a fuel delivery system of a vehicle having an engine during engine shut down periods, the method comprising: disposing a fuel delivery system within a fuel reservoir of a vehicle, the fuel delivery system, comprising: a pump being configured to provide fuel to the engine; a fluid pathway being in fluid communication with an outlet port of
25 the pump at one end; a regulator being disposed in the fluid pathway, the regulator regulating pressure of the fuel when the pump is pumping fuel into the fluid pathway; and a combination valve being disposed in the fluid pathway, the regulator being located between the combination valve and the outlet port of the pump, wherein the combination valve provides a check valve configured to

DP-309885

allow fuel flow in a first direction and a pressure relief valve configured to allow fuel flow in a second direction, the first direction being opposite to the second direction and the first direction being the same direction fuel is pumped in the fluid pathway by the pump; wherein the pressure relief valve is
5 configured to open when fuel in the fluid pathway exceeds a predetermined value when the engine of the vehicle is not running.

Another exemplary embodiment is a fuel delivery system for a vehicle having an engine, comprising: a pump being configured to provide fuel
10 to the engine; a fluid pathway being in fluid communication with an outlet port of the pump at one end; a regulator being disposed in the fluid pathway, the regulator regulating pressure of the fuel when the pump is pumping fuel into the fluid pathway; and a combination valve being disposed in the fluid pathway, the regulator being located between the combination valve and the outlet port of the
15 pump, wherein the combination valve provides a check valve configured to allow fuel flow in a first direction, a system pressure relief valve configured to allow fuel flow in a second direction, and a pump pressure relief valve configured to allow fuel flow in the first direction, the first direction being opposite to the second direction and the first direction being the same direction
20 fuel is pumped in the fluid pathway by the pump, wherein the pump pressure relief valve is configured to open at a pressure value higher than the pressure required to open the check valve.

Yet another exemplary embodiment is a fuel delivery system for
25 a vehicle having an engine, comprising: a pump being configured to provide fuel to the engine, the pump having an outlet port; a combination valve being disposed proximate to the outlet port and being in fluid communication with the pump, wherein the combination valve provides a check valve configured to allow fuel flow in a first direction, a pump pressure relief valve configured to

DP-309885

allow fuel flow in the first direction, the first direction being the direction fuel is pumped to the engine, wherein the pump pressure relief valve is configured to open at a pressure value higher than the pressure required to open the check valve.

5

The above-described and other features and advantages of the present invention will be appreciated and understood by those skilled in the art from the following detailed description, drawings, and appended claims.

10 BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a schematic view of a fuel delivery system;

Figure 2 is a cross sectional view of a combination valve constructed in accordance with an exemplary embodiment of the present invention;

15 Figure 3 is a schematic view of a fuel delivery system constructed in accordance with an exemplary embodiment of the present invention;

20 invention; and

Figure 5 is a cross sectional view of yet another combination valve constructed in accordance with an exemplary embodiment of the present invention.

25 DETAILED DESCRIPTION OF EXEMPLARY EMBODIMENTS

Disclosed herein is an apparatus and system that allows for relief of fuel in fuel pumping system when certain pressures are encountered. In accordance with exemplary embodiments of the present invention multiple valves are combined into a single unit or device thereby reducing costs and

DP-309885

points of connection for the valves. The apparatus and systems disclosed herein allow for fuel to be relieved under certain pressure situations without adversely affecting the starting sequence of an engine the system supplies fuel to.

Referring now to Figure 1, a portion of a typical fuel delivery
5 system or modular reservoir assembly 10 is illustrated schematically. The modular reservoir assembly 10 is, as is known in the related arts, positioned within a fuel tank of a vehicle (not shown) for delivering fuel to an engine of a vehicle. The modular reservoir assembly comprises a bucket 12 in which a fuel pump 14, a filter 16 and a regulator 18 are housed. The bucket is inserted
10 within the fuel tank or fuel reservoir and provides the necessary fluid paths for the fuel pump to be able to draw and pump fuel to the engine. Accordingly, the fuel pump is in fluid communication with fuel in the fuel tank. During an engine starting event and/or engine running event, fuel pump 14 provides fuel to the engine by pumping fuel to the filter, the regulator, and through a cover 20 by
15 passing fuel through a plurality of conduits, in the direction of arrows 22, which ultimately provides fuel to the engine of the vehicle.

As is known in the related arts the regulator is provided to regulate the pressure of the pumped fuel in accordance with predetermined tolerances or pressures. Thus, the regulator ensures that the pumped fuel does
20 not exceed a certain pressure.

In order to provide unhindered flow of fuel in the direction of arrows 22, a check valve 24 is positioned within fuel pump 14. Check valve 24 is configured to allow fuel flow and the direction of arrow 22 while preventing flow of fuel in a reverse direction or back into the fuel pump. An example of
25 such a check valve is described in commonly owned and assigned United States patent application serial number 09/992,079 filed on November 19, 2001, the contents of which are incorporated herein by reference thereto.

DP-309885

As discussed above, it is desirable to provide an overpressure valve to allow for expanding heated fuel to escape from the fuel line back into the fuel reservoir during vehicle shut down. However, since the check valve is typically a valve which allows flow therethrough under a first set of conditions or pressures, while preventing back flow, an additional valve location is required for this feature since the flow of an overpressure valve in the fuel circuit will be in the opposite direction of the check valve. One attempt to provide this feature in the system illustrated in Figure 1 is adapt the regulator to control the fuel pressure in the circuit during vehicle shut down. However, such a configuration can require costly processing modifications to be made to the regulator to prevent a loss of pressure in the fuel rail.

Moreover, the pressure relief of the modified regulator must be related to the pressure setting of the regulator which as discussed herein may not be the same pressure at which the over pressure relief is desired.

Referring now to Figure 2, and in accordance with an exemplary embodiment of the present invention, a combination fuel system pressure valve and forward check valve 30 is illustrated. Valve 30 provides both a system overpressure relief valve and a check valve without requiring a costly regulator. This valve design is cost efficient through the use of combining the inner housing of the overpressure valve function with the outer member of the fuel line/forward flow check valve function. In addition, and since the two valves are combined into one unit there is only one installation interface while two separate and distinct flow paths are provided, which typically would require at least two installation interfaces.

Valve 30 includes a valve housing 32 extending axially and is configured to be disposed in or become part of one of the conduits of the modular reservoir assembly illustrated in Figure 3. The valve housing has a body portion 34 that is generally tubular in shape and has a generally circular

DP-309885

cross-sectional shape. Of course, other configurations (e.g., square, hexagonal, etc.) are contemplated to be within the scope of the exemplary embodiments of the present invention. The body portion extends axially and has a passageway 36 extending axially therethrough. The valve housing is made of a rigid
5 material such as metal, plastic, or brass. It should also be appreciated that the valve housing is a monolithic structure being integral, unitary, and one-piece.

Disposed within passageway 36 is a pressure valve 38. The pressure valve 38 comprises a body portion 40 which is configured to be axially received within passageway 36. Body portion 40 is configured to have an
10 annular ring or shoulder portion 42 configured to engage a biasing member 44 that is positioned between shoulder 42 and a portion of a valve seat member 46 of body portion 34. Body portion 40 also comprises a fluid flow path or conduit 48 which will allow fluid to pass therethrough when body portion 40 is moved in the direction of arrow 50 by a pressure force sufficient to overcome the
15 biasing force of biasing member 44.

In order to provide the sealing of valve 38 in the position illustrated in Figure 2, an O-ring or sealing member 52 is disposed within a cavity of body portion 40 for engagement or sealing against a portion of valve seat 46.

20 Body portion 40 further comprises an inner passageway 54, which is configured to receive a forward check valve 56. The forward check valve comprises a body portion 58 which is configured to be axially received within passageway 54 for movement therein. Body portion 58 is configured to have an annular ring or shoulder portion 60 configured to engage a biasing
25 member 62 that is positioned between shoulder 60 and a portion of a valve seat member 64 of body portion 40. Body portion 58 also comprises a fluid flow path or conduit 66 which will allow fluid to pass therethrough when body

DP-309885

portion 58 is moved in the direction of arrow 68 by a pressure force sufficient to overcome the biasing force of biasing member 62. In order to provide the sealing of valve 56 in the position illustrated in Figure 2, an O-ring or sealing member 70 is disposed within a cavity of body portion 58 for engagement or
5 sealing against a portion of valve seat 64.

An example of body portion 58 is described and shown as the “valve member” of commonly owned and assigned United States Patent Applications serial numbers 09/935,079; 09/972,289; and 09/992,079 filed August 22, 2001, September 20, 2001 and November 19, 2001 respectively.
10 The contents of which are incorporated herein by reference thereto.

Referring now to Figure 3, and in accordance with exemplary embodiments of the present invention, a schematic illustration of a fuel delivery system 80 is provided. In an exemplary embodiment, combination fuel system pressure valve and forward check valve 30 is employed and the check valve is
15 removed from its location at the fuel pump. As illustrated in Figure 3, combination fuel system pressure valve and forward check valve 30 is positioned physically above regulator 18 and fuel pump 14. Accordingly, the following advantages are found due to the location of combination fuel system pressure valve and forward check valve 30.

20 As discussed above, an advantage of this embodiment is that valve 30 contains both checking and fuel system overpressure protection features. In addition, the location of this combination valve is above the fuel pressure regulator in a single line forward system. This system architecture eliminates a requirement of the regulator configured to check fuel pressure.
25 This, in turn, allows for a low-cost pressure relief type valve to be used in place of the more costly regulators. For example, regulators in use today that provide

DP-309885

fuel pressure checking features typically require expensive lapping operations to produce good surface finishes for sealing system pressure.

Thus, a regulator in this system can be configured to only regulate fuel pressure during a fuel pumping event. For example, the regulator
5 can be set to relieve at fuel pressures of approximately 400kPa. Of course, pressure thresholds greater than or less than the aforementioned values are contemplated to be within the scope of the present invention.

Another advantage of this system is that while the regulator still remains it is effectively removed from the fuel line circuit on vehicle shut-down
10 because the combination valve is physically above the regulator in the fuel circuit and since the combination valve does not set the system regulation pressure, it can be set to relieve well above the system pressure while still providing the desired system integrity. For example, above the 400 kPa relief setting of the regulator, which is specifically tied to the vehicle requirements
15 such as fuel injector thresholds. An exemplary pressure threshold for the check valve is approximately 20 kPa while the pressure threshold for the relief valve is 600 kPa. Of course, pressure thresholds greater than or less than the aforementioned values for opening combination valve 30 are contemplated to be within the scope of the present invention.

20 Accordingly, this higher opening pressure of the overpressure valve 38 requires pressure in the fuel rail to achieve a higher level before any fuel is bled off through valve 38. This, in turn, keeps more fuel in the line between the check valve 56 and the engine fuel rail downstream of the check valve on vehicle shutdown. This eliminates or reduces the vacuum conditions
25 which may occur in systems using the regulator to provide the relief valve feature, which may be exacerbated by the cooling of the fuel after fuel has been bled off via a relief valve set at a lower value because it is tied to the regulator

DP-309885

setting. By eliminating these vacuum conditions, the start times and start time variations are reduced.

Once the pump is turned on during engine crank the check valve opens and the rail pressure returns to a pressure set by the regulator.

5 Referring now to Figure 4, an alternative embodiment is illustrated. Here, a combination fuel system pressure valve, forward check valve and pump pressure valve 90 is illustrated. Combination valve 90 is also contemplated for use in the system depicted in Figure 3 as well as the same location (physically above the regulator in the fuel system).

10 This valve design is similar to valve 30 in that a forward check valve 56 and system pressure valve 38 are provided. However, outer body portion 34 is configured to be received within an inner opening 92 of yet another outer housing 94, thereby providing a third valve combined into the assembly. Again, the design illustrated is cost efficient through the use of
15 combining the inner housing of the overpressure valve function with the outer member of the fuel line/forward flow check valve function as well as the combination of outer housing 94 and body portion 34 to provide yet another valve 96 for a fluid path, which in this embodiment configured to a pump overpressure release. In this embodiment valve 96 is configured to provide a
20 release at a pressure that is above the pressure required to open forward check valve

In this embodiment body portion 34 is configured to have an annular ring or shoulder portion 98 configured to engage a biasing member 100 that is positioned between shoulder 98 and a portion of a valve seat member 102
25 of outer housing 94. Body portion 34 also comprises a fluid flow path or conduit (not shown) which will allow fluid to pass therethrough when body

DP-309885

portion 34 is moved in the direction of arrow 104 by a pressure force sufficient to overcome the biasing force of biasing member 100, which will be greater than the force required to overcome biasing member 62 of the forward check valve.

5 Therefore, and since the three valves are combined into one unit (valve 90) there is only one installation interface while three separate valves are provided, which typically would require at least three installation interfaces. Moreover, and as illustrated in Figure 3, the positioning of the valve removes the valve from the fuel pump and places them in the modular reservoir assembly
10 unit.

 The use of combination valve 30 or 90 above the regulator requires only one pre-tested valve assembly to be installed above the fuel pump, rather than the typical installation of components for two or three separate valves. As described above with regard to Figure 3, the location of either
15 combination valve 30 or 90 places the check valve above the regulator. This effectively removes the regulator from the fuel circuit on vehicle shutdown.

 Referring now to Figure 5 another alternative embodiment is illustrated. In this embodiment, a combination pump overpressure protection and forward check valve 120 is provided. Here a forward check valve 56 as
20 discussed with regard to the embodiments of Figures 2 and 4 is combined with a pump overpressure valve 96 discussed with regard to Figure 4. The elements of combination pump overpressure protection and forward check valve 120 are similar to those of valve 30 however, the relief direction of valve 96 is opposite to that of valve 38 discussed with regard to Figure 2. As also discussed above
25 valve 96 is configured to provide a release at a pressure that is above the pressure required to open forward check valve 56. In addition, an exemplary

DP-309885

location of combination valve 120 would be the same location as the forward flow check valve illustrated in Figure 1.

While the invention has been described with reference to one or more exemplary embodiments, it will be understood by those skilled in the art
5 that various changes may be made and equivalents may be substituted for elements thereof without departing from the scope of the invention. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the invention without departing from the essential scope thereof. Therefore, it is intended that the invention not be limited to the
10 particular embodiment disclosed as the best mode contemplated for carrying out this invention, but that the invention will include all embodiments falling within the scope of the appended claims. It should also be noted that the terms "first", "second", and "third" and the like may be used herein to modify elements performing similar and/or analogous functions. These modifiers do not imply a
15 spatial, sequential, or hierarchical order to the modified elements unless specifically stated.
